Chae et. al. (1995) have studied the concept of $\alpha$-strongly $\theta$ continuous functions and ( $\alpha, \theta$ )-closed graph. The aim of this paper is to investigate several new characterizations and properties of $\alpha$-strongly $\theta$ continuous functions and ( $\alpha, \theta$ )-closed graph. Also, we define a new type of functions called $\alpha \theta$-open functions, which is stronger than quasi $\alpha$-open and hence strongly $\alpha$-open, and we obtain some characterizations and properties for it. It is shown that the graph of $f, G(f)$ is $(\alpha, \theta)$-closed graph if and only if for each filter base $\Psi$ in $\mathrm{X} \quad \theta$-converging to some p in X such that $\mathrm{f}(\Psi) \alpha$-converges to some q in Y holds, $\mathrm{f}(\mathrm{p})=\mathrm{q}$.
Keywords: $\alpha$-strongly $\theta$-continuity, $\alpha \theta$-open function and ( $\alpha, \theta$ )-closed graph.

## 1. Introduction

Njastad (1965) introduced and investigated the concept of $\alpha$-open sets. Chae et.al. (1995) have studied the concept of $\alpha$-strongly $\theta$-continuous functions. It is shown in Chae et. al. (1995) that the type of $\alpha$-strongly $\theta$ continuous function is stronger than a strongly $\theta$-continuous function [25] and a strongly $\alpha$-continuous function [12].

The purpose of the present paper is to investigate
i) Further characterizations and properties of $\alpha$-strongly $\theta$-continuous functions [7] and ( $\alpha, \theta$ )-closed graph [7].
ii) We define a new type of functions called $\alpha \theta$-open functions, which is stronger than quasi $\alpha$-open and hence strongly $\alpha$-open, and we obtain some characterizations and properties for it.

## 2. Preliminaries

Throughout the present paper, spaces always mean topological spaces on which no separation axiom is assumed unless explicitly stated. Let $E$ be a subset of a space $X$. The closure and the interior of $E$ are denoted by $\mathrm{Cl}(\mathrm{E})$ and $\operatorname{Int}(\mathrm{E})$, respectively. A subset E is said to be regular open (resp. $\alpha$-open [22] and semi-open [16]) if $\mathrm{E}=\operatorname{Int}(\mathrm{Cl}(\mathrm{E})$ ) (resp. $\mathrm{E} \subset$ $\operatorname{Int}(\mathrm{Cl}(\operatorname{Int}(\mathrm{E})))$ and $\mathrm{E} \subset \mathrm{Cl}(\operatorname{Int}(\mathrm{E})))$. A subset E is said to be $\theta$-open [34](resp. $\theta$-semi-open [26]) if for each $x \in E$, there exists an open (resp. semi-open) set U in X such that $\mathrm{x} \in \mathrm{U} \subset \mathrm{Cl}(\mathrm{U}) \subset \mathrm{E}$. The complement of each regular open (resp. $\alpha$-open, semi-open, $\theta$-open and $\theta$-semi-open) set is called regular closed (resp. $\alpha$-closed, semi-closed, $\theta$-closed, $\theta$-semi-closed). The set $\alpha \mathrm{Cl}(\mathrm{E})=\{\mathrm{p} \in \mathrm{X}: \mathrm{E} \cap \mathrm{H} \neq \phi$ for each $\alpha$-open set H containing p$\}$. A filter base $\Psi$ is said to be $\theta$-convergent [34](resp. $\alpha$-convergent [32]) to a point $x \in X$ if for each open (resp. $\alpha$-open) set $G$ containing $x$, there exists an $\mathrm{F} \in \Psi$ such that $\mathrm{F} \subset \mathrm{Cl}(\mathrm{G})$ (resp. $\mathrm{F} \subset \mathrm{G}$ ).

In [9], E is a feebly open set in X if there exists an open set U such that $\mathrm{U} \subset \mathrm{E} \subset \mathrm{sCl}(\mathrm{U})$, where sCl is the semi-closure operator. It is shown in [13] that a set is $\alpha$-open if and only if it is feebly open. It is well-known that
for a space $(X, \tau), X$ can be retopologized by the family $\tau^{\alpha}$ of all $\alpha$-open sets of $X$ [19] and also the family $\tau^{\theta}$ of all $\theta$-open set of $X$ [34], that is, $\tau^{\theta}$ (called $\theta$-topology) and $\tau^{\alpha}$ (called an $\alpha$-topology) are topologies on X , and it is obvious that $\tau^{\theta} \subset \tau \subset \tau^{\alpha}$. The family of all $\alpha$-open (resp. $\theta$-open and feebly-open) set of X is denoted by $\alpha \mathrm{O}(\mathrm{X})$ (resp. $\theta \mathrm{O}(\mathrm{X})$ and $\mathrm{FO}(\mathrm{X})$ ).

- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called strongly $\theta$-continuous [27] if for each $\mathrm{x} \in \mathrm{X}$ and each open set H of Y containing $f(\mathrm{x})$, there exists an open set G of X containing x such that $f(\mathrm{Cl}(\mathrm{G})) \subset \mathrm{H}$.
- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called strongly $\theta$-continuous [27] if for each open set H of Y , $f^{-1}(\mathrm{H})$ is $\theta$-open in X if and only if each closed set F of $\mathrm{Y}, f^{-1}(\mathrm{~F})$ is $\theta$-closed in X .
- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called $\alpha$-continuous [20] (resp. faintly continuous [18], completely $\alpha$-irresolute [21] and strongly $\alpha$-irresolute [12]) if for each open (resp. $\theta$-open, $\alpha$-open and $\alpha$-open) set H of $\mathrm{Y}, f^{-1}(\mathrm{H})$ is $\alpha$-open (resp. open, regular open and open) in $X$.
- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called semi-open [23] ( resp. $\alpha$-open [20], quasi $\alpha$-open [33], $\theta$ s-open[1], weakly $\theta$ s-open[1] and $s^{* *}$-open[2]) function if the image of each open (resp. open, $\alpha$-open, open, $\theta$-open and semi-open) set G of $\mathrm{X}, f$ $(\mathrm{G})$ is semi-open (resp. $\alpha$-open, open, $\theta$-semi-open, $\theta$-semi-open and open) in Y.
- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called pre-feebly-open[8]( resp. strongly $\alpha$-open [33] and $\alpha^{* *}$-open[2]) function if the image of each $\alpha$-open set G of $\mathrm{X}, f(\mathrm{G})$ is $\alpha$ open in Y.

It is clear that pre-feebly-open, strongly $\alpha$-open and $\alpha^{* *}$-open functions are equivalent.

- A subset $N$ of a space $X$ is said to be a $\theta$-neighborhood[5] of a point $x$ in $X$ if there exists an open set $G$ such that $x \in G \subset C l(G) \subset N$.
- $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called $\theta$-open function [5] if for each $\mathrm{x} \in \mathrm{X}$ and each $\theta$-neighborhood N of $\mathrm{x}, f(\mathrm{~N})$ is $\theta$-neighborhood of $f(\mathrm{x})$.
- A space X is said to be almost regular[31] if for each regularly closed set $R$ of $X$ and each point $x \notin R$, there exist disjoint open sets $U$ and $V$ such that $R \subset U$ and $x \in V$.
- A space $X$ is said to be $\alpha$-Hausdorff [12] if for any $x, y \in X, x \neq y$, there exist $\alpha$-open sets $G$ and $H$ such that $x \in G, y \in H$ and $G \cap H=\phi$. It is clear that $\alpha$-Hausdorff and Hausdorff are equivalent.
- A space $X$ is said to be $\theta$-compact [30] (resp. $\alpha$-compact [14]) if and only if every cover of $X$ by $\theta$-open (resp. $\alpha$-open ) sets has a finite subcover.
- A subset $S$ of a space $X$ is said to be quasi H-closed [28] relative to $X$ if each cover $\left\{E_{i}: i \in I\right\}$ of $S$ by open sets of $X$, there exists a finite subset $I_{0}$ of I such that $\mathrm{S} \subset \cup\left\{\mathrm{Cl}\left(\mathrm{E}_{\mathrm{i}}\right): \mathrm{i} \in \mathrm{I}_{0}\right\}$.
- A space $X$ is said to be quasi $H$-closed [28] if $X$ is quasi $H$-closed relative to X .
- A function $f: \mathrm{X} \rightarrow \mathrm{Y}$ is said to have $\theta$-closed[24](resp. s*-closed[17], semi-closed[11], $\theta$ s-closed[1], almost strongly $\theta$ s-closed[1] and strongly $\theta$ s-closed[1]) graph if and only if for each $\mathrm{x} \in \mathrm{X}$ and each $\mathrm{y} \in \mathrm{Y}$ such that $\mathrm{y} \neq f(\mathrm{x})$, there exists an open (resp. semi-open, semi-open, semi-open, semiopen and semi-open) $U$ containing $x$ in $X$ and an open (resp. open, semiopen, open, open and open) set V containing $f$ ( x ) in Y such that: $(\mathrm{Cl}(\mathrm{U}) \times \mathrm{Cl}(\mathrm{V})) \cap \mathrm{G}(f)=\phi$ \{resp. $(\mathrm{U} \times \mathrm{V}) \cap \mathrm{G}(f)=\phi,(\mathrm{U} \times \mathrm{V}) \cap \mathrm{G}(f)$ $=\phi,(\mathrm{Cl}(\mathrm{U}) \times \mathrm{V}) \cap \mathrm{G}(f)=\phi,(\mathrm{Cl}(\mathrm{U}) \times \operatorname{Int}(\mathrm{Cl}(\mathrm{V}))) \cap \mathrm{G}(f)=\phi$ and $(\mathrm{Cl}(\mathrm{U}) \times \mathrm{Cl}(\mathrm{V})) \cap \mathrm{G}(f)=\phi\}$.

## 3. $\alpha$-strongly $\theta$-continuity

Definition 3.1. A function $f: \mathrm{X} \rightarrow \mathrm{Y}$ is said to be $\alpha$-strongly $\theta$-continuous [7] if for each $\mathrm{x} \in \mathrm{X}$ and each $\alpha$-open set H of Y containing $f(\mathrm{x})$, there exists an open set U of X containing x such that $f(\mathrm{Cl}(\mathrm{U})) \subset \mathrm{H}$.

The proof of the following theorem is not hard and therefore, it is omitted.

Theorem 3.1. For a function $f:(\mathrm{X}, \tau) \rightarrow(\mathrm{Y}, \gamma)$, the following are equivalent:
i) $f$ is $\alpha$-strongly $\theta$-continuous;
ii) $f:\left(\mathrm{X}, \tau^{\theta}\right) \rightarrow(\mathrm{Y}, \gamma)$ is strongly $\alpha$-irresolute;
iii) For each point $\mathrm{x} \in \mathrm{X}$ and each filterbase $\Psi$ in $\mathrm{X} \theta$-converging to x , the filterbase $f(\Psi)$ converges to $f(\mathrm{x})$ in $(\mathrm{Y}, \alpha \mathrm{O}(\mathrm{Y}))$;
iv) For each point $x \in X$ and each net $\{x \lambda\}_{\lambda \in \nabla}$ in $X \quad \theta$-converging to $x$, the net $\left\{f\left\{\mathrm{x}_{\lambda}\right)\right\}_{\lambda \in \mathrm{V}}$ converges to $f(\mathrm{x})$ in ( $\mathrm{Y}, \alpha \mathrm{O}(\mathrm{Y})$ );
v) For each point $x \in X$ and each filterable $\Psi$ in $X \theta$-converging to $x$, the fiterbase $f(\Psi) \quad \alpha$-converges to $f(\mathrm{x})$ in ( $\mathrm{Y}, \gamma$ );
vi) For each point $x \in X$ and each net $\left\{x_{\lambda}\right\}_{\lambda \in \nabla}$ in $X \theta$-converging to $x$, the net $\{f\{\mathrm{x} \lambda)\}_{\lambda \in \mathrm{D}} \quad \alpha$-converges to $f(\mathrm{x})$ in (Y, $\gamma$ ).

Lemma 3.1. (Andrijevic [4]). Let E be a subset of a space ( $\mathrm{X}, \tau$ ). Then the following hold.

1) $\alpha \mathrm{Cl}(\mathrm{E})=\mathrm{E} \cup \mathrm{Cl}(\operatorname{Int}(\mathrm{Cl}(\mathrm{E})))$;
2) $\alpha \operatorname{Int}(\mathrm{E})=\mathrm{E} \cap \operatorname{Int}(\mathrm{Cl}(\operatorname{Int}(\mathrm{E})))$.

Theorem 3.2. For $f: \mathrm{X} \rightarrow \mathrm{Y}$, the following are equivalent:
a) $f$ is $\alpha$-strongly $\theta$-continuous;
b) $f\left(\mathrm{Cl}_{\theta}(\mathrm{E})\right) \subset f(\mathrm{E}) \cap \mathrm{Cl}(\operatorname{Int}(\mathrm{Cl}(f(\mathrm{E}))))$, for each subset E of X ;
c) $\mathrm{Cl}_{\theta}\left(f^{-1}(\mathrm{~W})\right) \subset f^{-1}(\mathrm{~W} \cup \mathrm{Cl}(\operatorname{Int}(\mathrm{Cl}(\mathrm{W})))$, for each subset W of Y ;
d) $f^{-1}\left(\mathrm{~W} \cap \operatorname{Int}(\mathrm{Cl}(\operatorname{Int}(\mathrm{W}))) \subset \operatorname{Int}_{\theta}\left(f^{-1}(\mathrm{~W})\right)\right.$, for each subset W of Y .

Proof. This follows from Lemma 3.1 and Theorem 2 of [7].

Theorem 3.3. If $f: \mathrm{X} \rightarrow \mathrm{Y}$ is $\alpha$-strongly $\theta$-continuous and if E is an open subset of X , then $f \mid \mathrm{E}: \mathrm{E} \rightarrow \mathrm{Y}$ is $\alpha$-strongly $\theta$-continuous.
Proof. Let H be any $\alpha$-open subset of Y. Since $f$ is $\alpha$-strongly $\theta$ continuous. By [7, Theorem 2], $f^{-1}(\mathrm{H}) \in \theta \mathrm{O}(\mathrm{X})$, so by Lemma 1.2.9 of $[1],(f \mid \mathrm{E})^{-1}(\mathrm{H})=f^{-1}(\mathrm{H}) \cap \mathrm{E} \in \theta \mathrm{O}(\mathrm{E})$. This implies that $f \mid \mathrm{E}: \mathrm{E} \rightarrow \mathrm{Y}$ is $\alpha$-strongly $\theta$-continuous.

The proof of the following result directly is true.
Theorem 3.4. For any two functions, $f: \mathrm{X} \rightarrow \mathrm{Y}$ and $g: \mathrm{Y} \rightarrow \mathrm{Z}$, the following are true:
i) if $f$ is $\alpha$-strongly $\theta$-continuous and $g$ is $\alpha$-continuous, then $g$ o $f$ is strongly $\theta$-continuous.
ii) if $f$ is faintly continuous and $g$ is $\alpha$-strongly $\theta$-continuous, then $g$ o $f$ is strongly $\alpha$-irresolute.

Theorem 3.5. Let $f: \mathrm{X} \rightarrow \mathrm{Y}$ be a function. If $g: \mathrm{Y} \rightarrow \mathrm{Z}$ is an $\alpha$-open bijection and $g$ of: X $\rightarrow \mathrm{Z}$ is $\alpha$-strongly $\theta$-continuous, then $f$ is strongly $\theta$ continuous.
Proof. Suppose $g$ is $\alpha$-open function. Let H be an open subset of Y, since $g$ is one to one and onto, then the set $g(\mathrm{H})$ is an $\alpha$-open subset of Z , since $g \circ f$ is $\alpha$-strongly $\theta$-continuous, it follows that $(g \circ f)^{-1}(g(\mathrm{H}))=f^{-1}(g$ $\left.{ }^{-1}(g(\mathrm{H}))\right)=f^{-1}(\mathrm{H})$ is $\theta$-open in X . Thus, $f$ is strongly $\theta$-continuous.

Theorem 3.6. If X is almost regular and $f: \mathrm{X} \rightarrow \mathrm{Y}$ is completely $\alpha$ irresolute function, then $f$ is $\alpha$-strongly $\theta$-continuous.
Proof. Let $H$ be an $\alpha$-open subset of Y. Since $f$ is completely $\alpha$ irresolute, $f^{-1}(\mathrm{H})$ is regular open in X and from the fact that a space X is almost regular if and only if for each $x \in X$ and each regular open set $f^{-1}(\mathrm{H})$ containing x , there exists a regular open set O such that $\mathrm{x} \in \mathrm{O} \subset \mathrm{Cl}(\mathrm{O}) \subset f^{-1}(\mathrm{H})$ [31, Theorem 2.2]. Therefore, $f^{-1}(\mathrm{H})$ is $\theta$-open in X and by [7, Theorem 2], $f$ is $\alpha$-strongly $\theta$-continuous.

Lemma 3.2 [10]. Let $\left\{X_{\lambda}: \lambda \in \Delta\right\}$ be a family of spaces and $U \lambda_{i}$ be a subset of $X \lambda_{\lambda_{\mathrm{i}}}$ for each $\mathrm{i}=1,2, \ldots, \mathrm{n}$. Then $\mathrm{U}=\prod_{i=1}^{n} \mathrm{U} \lambda_{i} \times \prod_{\lambda \neq \lambda_{l}} X_{\lambda}$ is $\alpha-$ open in $\prod_{\lambda \in \Delta} X \lambda$ if and only if $U \lambda_{i} \in \alpha O\left(X \lambda_{i}\right)$ for each $i=1,2, \ldots, n$.

Theorem 3.7. Let $g_{\lambda}: X_{\lambda} \rightarrow Y_{\lambda}$ be a function for each $\lambda \in \Delta$ and $\mathrm{g}: \Pi \mathrm{X}_{\lambda} \rightarrow \Pi \quad \mathrm{Y}_{\lambda}$ a function defined by $\left.g\left(\begin{array}{ll}\mathrm{x} & { }_{\lambda}\end{array}\right\}\right)=\left\{\begin{array}{lll}g_{\lambda} & \left.\left(\begin{array}{ll}\mathrm{x} & \\ \lambda\end{array}\right)\right\}\end{array}\right.$ for each $\left\{\mathrm{x}_{\lambda}\right\} \in \mathrm{X}_{\lambda}$. If $g$ is $\alpha$-strongly $\theta$-continuous, then $g_{\lambda}$ is $\alpha$-strongly $\theta$-continuous for each $\lambda \in \Delta$.
Proof. Let $\beta \in \Delta$ and $V_{\beta} \in \alpha O\left(Y_{\beta}\right)$. Then, by Lemma 3.2, $V=V_{\beta} \times$ $\prod_{\lambda \neq \beta} \mathrm{Y}_{\lambda}$ is $\alpha$-open in $\Pi \mathrm{Y}_{\lambda}$ and $g^{-1}(\mathrm{~V})=g^{-1}{ }_{\beta}\left(\mathrm{V}_{\beta}\right) \times \prod_{\lambda \neq \beta} \mathrm{X}_{\lambda}$ is $\theta$-open in $\Pi \mathrm{X}_{\lambda}$. From Lemma 3.2, $g \beta^{-1}\left(\mathrm{~V}_{\beta}\right) \in \theta \mathrm{O}(\mathrm{X})$. Therefore, $g \beta$ is $\alpha$-strongly $\theta$-continuous.

Remark 3.1. It was known in [6, Example 2.2] that $\mathrm{V} \in \alpha \mathrm{O}(\mathrm{X} \times \mathrm{Y})$ may not, generally, be a union of sets of the form $\mathrm{A} \times \mathrm{B}$ in the product space $\mathrm{X} \times \mathrm{Y}$, where $A \in \alpha O(X)$ and $B \in \alpha O(Y)$. Therefore, the converse of Theorem 3.8 may not be true, generally.

Theorem 3.8. Let $g: X \rightarrow Y_{1} \times Y_{2}$ be $\alpha$-strongly $\theta$-continuous function and $f_{\mathrm{i}}: \mathrm{X} \rightarrow \mathrm{Y}_{\mathrm{i}}$ be coordinate functions, i.e. for $\mathrm{x} \in \mathrm{X}, g(\mathrm{x})=\left(\mathrm{x}_{1}, \mathrm{x}_{2}\right), f_{\mathrm{i}}(\mathrm{x})=$ $\mathrm{X}_{\mathrm{i}}, \mathrm{i}=1$, 2. Then $f_{\mathrm{i}}: \mathrm{X} \rightarrow \mathrm{Y}_{\mathrm{i}}$ is $\alpha$-strongly $\theta$-continuous for $\mathrm{i}=1,2$.
Proof. Let x be any point in X and $\mathrm{H}_{1}$ be any $\alpha$-open set in $\mathrm{Y}_{1}$ containing $f_{1}(\mathrm{x})=\mathrm{x}_{1}$, then by Lemma 3.2, $\mathrm{H}_{1} \times \mathrm{Y}_{2}$ is $\alpha$-open in $\mathrm{Y}_{1} \times \mathrm{Y}_{2}$, which
contain ( $\mathrm{x}_{1}, \mathrm{x}_{2}$ ). Since $g$ is $\alpha$-strongly $\theta$-continuous, there exists an open set U containing x such that $g(\mathrm{Cl}(\mathrm{U})) \subset \mathrm{H}_{1} \times \mathrm{Y}_{2}$. Then $f_{1}(\mathrm{Cl}(\mathrm{U})) \times f_{2}(\mathrm{Cl}(\mathrm{U}))$ $\subset \mathrm{H}_{1} \times \mathrm{Y}_{2}$. Therefore, $f_{1}(\mathrm{Cl}(\mathrm{U})) \subset \mathrm{H}_{1}$. Hence $f_{1}$ is $\alpha$-strongly $\theta$ continuous.
Lemma 3.3. Let $X_{1}, X_{2}, \ldots, X_{n}$ be $n$ topological spaces and $X=\prod_{i=1}^{n} X_{i}$.
Let $\mathrm{E}_{\mathrm{i}} \in \theta \mathrm{O}\left(\mathrm{X}_{\mathrm{i}}\right)$, for $\mathrm{i}=1,2, \ldots, \mathrm{n}$. Then $\prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}} \in \theta \mathrm{O}\left(\prod_{i=1}^{n} X_{i}\right)$.
Proof. Let $\left(x_{1}, x_{2}, \ldots, x_{n}\right) \in \prod_{i=1}^{n} E_{i}$, then $x_{i} \in E_{i}$, for $i=1,2, \ldots$, n. Since $E_{i} \in \theta O\left(X_{i}\right)$, for $i=1,2, \ldots, n$. Then, there exist open sets $U_{i}$, for $i=1,2$, $\ldots, n$ such that $x_{i} \in U_{i} \subset \mathrm{Cl}\left(\mathrm{U}_{\mathrm{i}}\right) \subset \mathrm{E}_{\mathrm{i}}$, for $\mathrm{i}=1,2, \ldots$, n . Therefore, $\left(\mathrm{x}_{1}, \mathrm{x}_{2}\right.$, $\left.\ldots, \mathrm{x}_{\mathrm{n}}\right) \in \mathrm{U}_{1} \times \mathrm{U}_{2} \times \ldots \times \mathrm{U}_{\mathrm{n}} \subset \mathrm{Cl}\left(\mathrm{U}_{1}\right) \times \mathrm{Cl}\left(\mathrm{U}_{2}\right) \times \ldots \times \mathrm{Cl}\left(\mathrm{U}_{\mathrm{n}}\right)=\mathrm{Cl}_{\mathrm{X} 1} \times \mathrm{X} 2 \times \ldots \times \mathrm{Xn}$ $\left(\mathrm{U}_{1} \times \mathrm{U}_{2} \times \ldots \times \mathrm{U}_{\mathrm{n}}\right) \subset \prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}} \quad$ and $\quad \prod_{i=1}^{n} \mathrm{U}_{\mathrm{i}} \in \tau\left(\prod_{i=1}^{n} \mathrm{X}_{\mathrm{i}}\right)$. Hence $\prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}}$ is $\theta$-open set in $\prod_{i=1}^{n} \mathrm{X}_{\mathrm{i}}$.

Theorem 3.9. Let $X_{1}, X_{2}, \ldots, X_{n}$ and $Z$ be topological spaces and $f: \prod_{i=1}^{n} \mathrm{Xi} \rightarrow Z$. If given any point p of $\prod_{i=1}^{n} \mathrm{X}_{\mathrm{i}}$, and given any $\alpha$-open set U in Z containing $f(\mathrm{p})$, there exist $\theta$-open sets $\mathrm{E}_{\mathrm{i}}$ in $\mathrm{X}_{\mathrm{i}}$ for $\mathrm{i}=1,2, \ldots, \mathrm{n}$ such that $\mathrm{p} \in \prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}}$ and $f\left(\prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}}\right) \subset \mathrm{U}$. Then $f$ is $\alpha$-strongly $\theta$ continuous.

Proof. Let $\mathrm{p} \in \prod_{i=1}^{n} \mathrm{X}_{\mathrm{i}}$ and U be any $\alpha$-open set in Z containing $f(\mathrm{p})$. By hypothesis, there exist $\theta$-open sets $E_{i}$ in $X_{i}$ for $i=1,2, \ldots, n$ such that $p \in$

Therefore, by Lemma 3.3, $\prod_{i=1}^{n} \mathrm{E}_{\mathrm{i}} \in \theta \mathrm{O}\left(\prod_{i=1}^{n} \mathrm{X}_{\mathrm{i}}\right)$, for $\mathrm{i}=1,2, \ldots, \mathrm{n}$. Thus, $f$ is $\alpha$-strongly $\theta$-continuous.

## 4. $\alpha \theta$-open Functions.

In this section we define a new type of functions called $\alpha \theta$-open function and we find some characterization and properties for it.

Definition 4.1. A function $f: \mathrm{X} \rightarrow \mathrm{Y}$ is called $\alpha \theta$-open if and only if for each $\alpha$-open set G in $\mathrm{X}, f(\mathrm{G}) \in \theta \mathrm{O}(\mathrm{Y})$.

It follows immediately that every $\alpha \theta$-open functions is quasi $\alpha$ open and hence strongly $\alpha$-open, the converse is not true as seen from the following example.

Example 4.1. Let $\mathrm{X}=\{\mathrm{a}, \mathrm{b}, \mathrm{c}, \mathrm{d}\}$ and $\tau=\{\mathrm{X}, \phi,\{\mathrm{a}\},\{\mathrm{c}\},\{\mathrm{a}, \mathrm{b}\},\{\mathrm{a}, \mathrm{c}\}$, $\{\mathrm{a}, \mathrm{b}, \mathrm{c}\},\{\mathrm{a}, \mathrm{c}, \mathrm{d}\}\}$. The identity function $i:(\mathrm{X}, \tau) \rightarrow(\mathrm{X}, \tau)$ is strongly $\alpha-$ open, but it is not $\alpha \theta$-open function since $\{\mathrm{a}\} \in \alpha \mathrm{O}(\mathrm{X}, \tau)$, but $f(\{\mathrm{a}\})=\{\mathrm{a}\}$ $\notin \theta \mathrm{O}(\mathrm{X}, \tau)$.

We find some characterizations and properties of $\alpha \theta$-open functions.

Theorem 4.1. For any bijection function $f: \mathrm{X} \rightarrow \mathrm{Y}$, the following are equivalent:
i) The inverse function $f^{-1}: \mathrm{Y} \rightarrow \mathrm{X}$ is $\alpha$-strongly $\theta$-continuous;
ii) $f: \mathrm{X} \rightarrow \mathrm{Y}$ is $\alpha \theta$-open function.

Proof. Follows from their definitions.
Theorem 4.2. For a function $f: \mathrm{X} \rightarrow \mathrm{Y}$, the following are equivalent:
a) $f$ is $\alpha \theta$-open function;
b) $f(\alpha \operatorname{Int}(\mathrm{E})) \subset \operatorname{Int}_{\theta}(f(\mathrm{E}))$, for each subset E of X ;
c) $\alpha \operatorname{Int}\left(f^{-1}(\mathrm{~W})\right) \subset f^{-1}\left(\operatorname{Int}_{\theta}(\mathrm{W})\right)$, for each subset W of Y ;
d) $f^{-1}\left(\mathrm{Cl}_{\theta}(\mathrm{W})\right) \subset \alpha \mathrm{Cl}\left(f^{-1}(\mathrm{~W})\right)$, for each subset W of Y .

Proof. (a) $\Rightarrow$ (b). Suppose $f$ is $\alpha \theta$-open function and $\mathrm{E} \subset \mathrm{X}$. Since $\alpha \operatorname{Int}(\mathrm{E}) \subset$ $\mathrm{E}, f(\alpha \operatorname{Int}(\mathrm{E})) \in \theta \mathrm{O}(\mathrm{Y})$ and $f(\alpha \operatorname{Int}(\mathrm{E})) \subset f(\mathrm{E})$ and hence $f(\alpha \operatorname{Int}(\mathrm{E})) \subset$ $\operatorname{Int}_{\theta}(f(\mathrm{E}))$.
(b) $\Rightarrow$ (c). Let $\mathrm{W} \subset \mathrm{Y}$. Then $f^{-1}(\mathrm{~W}) \subset \mathrm{X}$. Therefore, we apply (b), we obtain $f\left(\alpha \operatorname{Int}\left(f^{-1}(\mathrm{~W})\right)\right) \subset \operatorname{Int}_{\theta}\left(f\left(f^{-1}(\mathrm{~W})\right)\right)$. Then, $\alpha \operatorname{Int}\left(f^{-1}(\mathrm{~W})\right) \subset f^{-1}\left(\operatorname{Int}_{\theta}\right.$ (W)).
$(\mathbf{c}) \Rightarrow(\mathbf{d})$. Let $\mathrm{W} \subset \mathrm{Y}$, then apply (c) to $\mathrm{Y} \backslash \mathrm{W}$, we get $\alpha \operatorname{Int}\left(f^{-1}(\mathrm{Y} \backslash \mathrm{W})\right) \subset f$ ${ }^{-1}\left(\operatorname{Int}_{\theta}(\mathrm{Y} \backslash \mathrm{W})\right)$. Then, $\alpha \operatorname{Int}\left(\mathrm{X} \backslash f^{-1}(\mathrm{~W})\right) \subset f^{-1}\left(\mathrm{Y} \backslash \mathrm{Cl}_{\theta}(\mathrm{W})\right)$, which implies that $\mathrm{X} \backslash \alpha \mathrm{Cl}\left(f^{-1}(\mathrm{~W})\right) \subset \mathrm{X} \backslash f^{-1}\left(\mathrm{Cl}_{\theta}(\mathrm{W})\right)$. Hence $f^{-1}\left(\mathrm{Cl}_{\theta}(\mathrm{W})\right) \subset$ $\alpha \mathrm{Cl}\left(f^{-1}(\mathrm{~W})\right)$.
$(\mathbf{d}) \Rightarrow(\mathbf{a})$. Let G be any $\alpha$-open set in X . Then $\mathrm{Y} \backslash f(\mathrm{G}) \subset \mathrm{Y}$, apply (d), we obtain $f^{-1}\left(\mathrm{Cl}_{\theta}(\mathrm{Y} \backslash f(\mathrm{G}))\right) \subset \alpha \mathrm{Cl}\left(f^{-1}(\mathrm{Y} \backslash f(\mathrm{G}))\right)$. Then $f^{-1}(\mathrm{Y} \backslash \operatorname{Int} \theta(f$ $(\mathrm{G}))) \subset \alpha \mathrm{Cl}(\mathrm{X} \backslash \mathrm{G})$. Which implies that $\mathrm{X} \backslash f^{-1}(\operatorname{Int} \theta(f(\mathrm{G}))) \subset \mathrm{X} \backslash \operatorname{Int} \mathrm{G}$ $=\mathrm{X} \backslash \mathrm{G}$. Therefore, $\mathrm{G} \subset f^{-1}$ (Inte( $\left.f(\mathrm{G})\right)$ ). Then, $f(\mathrm{G}) \subset \operatorname{Int} \theta(f$ $(\mathrm{G})$ ). Therefore, $f(\mathrm{G}) \in \theta \mathrm{O}(\mathrm{Y})$. which completes the proof.

Remark 4.1. Let $f: \mathrm{X} \rightarrow \mathrm{Y}$ be a bijective function. Then, $f$ is $\alpha \theta$-open function if and only if $f(\mathrm{~F}) \in \theta \mathrm{C}(\mathrm{Y})$, for each $\alpha$-closed set F in X .

Theorem 4.3. If Y is a regular space, then each $\mathrm{s}^{* *}$-open function is $\alpha \theta$ open.
Proof. Let $\mathbf{G}$ be any $\alpha$-open subset of $\mathbf{X}$, then it is semi-open. Since $f$ is $\mathrm{s}^{* *}$-open function. Therefore, $f(\mathrm{G})$ is open in Y. But Y is a regular space, then by [1, Lemma 1.2.8] $f(\mathrm{G})$ is $\theta$-open in Y.

Theorem 4.4. If a function $f: \mathrm{X} \rightarrow \mathrm{Y}$ is $\alpha \theta$-open and $\mathrm{E} \subset \mathrm{X}$ is an open set in X , then the restriction $f \mid \mathrm{E}: \mathrm{E} \rightarrow \mathrm{Y}$ is $\alpha \theta$-open function.
Proof. Let $H$ be any $\alpha$-open set in the open subspace E. Then, by [15, Theorem 3.7], H is $\alpha$-open in X . Since $f$ is $\alpha \theta$-open function. Therefore, $f$ $(\mathrm{H})$ is $\theta$-open in Y. Hence $f \mid \mathrm{E}$ is $\alpha \theta$-open function.

Theorem 4.5. Let $f: \mathrm{X} \rightarrow \mathrm{Y}$ be a function and $\{\mathrm{E} \alpha: \alpha \in \nabla\}$ be an open cover of X . If the restriction $f \mid \mathrm{E}_{\alpha}: \mathrm{E}_{\alpha} \rightarrow \mathrm{Y}$ is $\alpha \theta$-open function for each $\alpha \in \nabla$, then $f$ is $\alpha \theta$-open function.
Proof. Let H be any $\alpha$-open set in X. Therefore, by [15, Theorem 3.4], H $\cap$ $\mathrm{E}_{\alpha}$ is $\alpha$-open in the subspace $\mathrm{E}_{\alpha}$ for each $\alpha \in \nabla$. Since $f \mid \mathrm{E}_{\alpha}$ is $\alpha \theta$-open function $\left(f \mid \mathrm{E}_{\alpha}\right)\left(\mathrm{H} \cap \mathrm{E}_{\alpha}\right)$ is $\theta$-open in Y and hence $f(\mathrm{H})=\cup\left\{\left(f \mid \mathrm{E}_{\alpha}\right)\right.$ ( $\mathrm{H} \cap \mathrm{E}_{\alpha}$ ) : $\alpha \in \nabla$ \}is $\theta$-open in Y . This shows that $f$ is $\alpha \theta$-open function.

Theorem 4.6. A function $f: \mathrm{X} \rightarrow \mathrm{Y}$ is $\alpha \theta$-open if and only if for each subset S of Y and any $\alpha$-closed set F in X containing $f^{-1}(\mathrm{~S})$, there exists a $\theta$ closed set M in Y containing S such that $f^{-1}(\mathrm{M}) \subset \mathrm{F}$.
Proof. Suppose that $f$ is $\alpha \theta$-open function. Let $\mathrm{S} \subset \mathrm{Y}$ and F be an $\alpha$ closed set in X containing $f^{-1}(\mathrm{~S})$. Put $\mathrm{M}=\mathrm{Y} \backslash f(\mathrm{X} \backslash \mathrm{F})$, then M is $\theta$ closed in Y and since $f^{-1}(\mathrm{~S}) \subset \mathrm{F}$, we have $\mathrm{S} \subset \mathrm{M}$. Since $f$ is $\alpha \theta$-open function and F is $\alpha$-closed in $\mathrm{X}, \mathrm{M}$ is $\theta$-closed in Y. Obviously $f^{-1}$ (M) $\subset \mathrm{F}$.

Conversely, let G be any $\alpha$-open subset of X and put $\mathrm{S}=\mathrm{Y} \backslash f(\mathrm{G})$. Then, $\mathrm{X} \backslash \mathrm{G}$ is $\alpha$-closed set containing $f^{-1}(\mathrm{~S})$. By hypothesis, there exists a $\theta$-closed set M in Y containing S such that $f^{-1}(\mathrm{M}) \subset \mathrm{X} \backslash \mathrm{G}$. Thus, we have $f(\mathrm{G}) \subset \mathrm{Y} \backslash \mathrm{M}$. On the other hand, we have $f(\mathrm{G})=\mathrm{Y} \backslash \mathrm{S} \supset \mathrm{Y} \backslash \mathrm{M}$ and hence $f(\mathrm{G})=\mathrm{Y} \backslash \mathrm{M}$. Consequently, $f(\mathrm{G})$ is $\theta$-open in Y and $f$ is $\alpha \theta$-open function.

## 5. Functions with ( $\alpha, \theta$ )-closed graph

In this section we investigate several new properties of $(\alpha, \theta)$-closed graph [7].
Definition 5.1[7]. Let $\mathrm{G}(f)=\{(\mathrm{x}, f(\mathrm{x})): \mathrm{x} \in \mathrm{X}\}$ be the graph of $f: \mathrm{X} \rightarrow \mathrm{Y}$ then $\mathrm{G}(f)$ is said to be $(\alpha, \theta)$-closed with respect to $\mathrm{X} \times \mathrm{Y}$, if for each point ( $\mathrm{x}, \mathrm{y}$ ) $\notin \mathrm{G}(f)$, there exists an open set U and an $\alpha$-open set H containing x and y , respectively such that $f(\mathrm{Cl}(\mathrm{U})) \cap \mathrm{H}=\phi$.

The following diagram is an enlargement of the diagram 4.1.1 of [1]. Note that none of the implications is reversible

$\theta$ s-closed graph

$\theta$ s-closed graph strongly $\theta$ s-closed grapl- $\theta$-closed graph $-(\alpha, \theta)$-closed graph

Diagram 5.1

Example 5.1. Let $\mathrm{X}=\{\mathrm{a}, \mathrm{b}, \mathrm{c}\}$ and $\tau=\{\phi, \mathrm{X},\{\mathrm{a}\},\{\mathrm{a}, \mathrm{b}\},\{\mathrm{a}, \mathrm{c}\}\}$, then the function $f:(\mathrm{X}, \tau) \rightarrow(\mathrm{X}, \tau)$ is defined as: $f(\mathrm{x})=\mathrm{a}$, for each $\mathrm{x} \in \mathrm{X}$, has $\theta$-closed graph, which has not $(\alpha, \theta)$-closed graph.

Theorem 5.1. If $f: \mathrm{X} \rightarrow \mathrm{Z}$ is a function with ( $\alpha, \theta$ )-closed graph, and $g: \mathrm{Y}$ $\rightarrow \mathrm{Z}$ is $\alpha$-strongly $\theta$-continuous functions, then the set $\{(\mathrm{x}, \mathrm{y}): f(\mathrm{x})=g$ (y) $\}$ is $\theta$-closed in $\quad \mathrm{X} \times \mathrm{Y}$.

Proof. Let $\mathrm{E}=\{(\mathrm{x}, \mathrm{y}): f(\mathrm{x})=g(\mathrm{y})\}$. If $(\mathrm{x}, \mathrm{y}) \in \mathrm{X} \times \mathrm{Y} \backslash \mathrm{E}$, then $f(\mathrm{x}) \neq g$ (y). Hence $(\mathrm{x}, g(\mathrm{y})) \in(\mathrm{X} \times \mathrm{Z}) \backslash \mathrm{G}(f)$. Since $f$ has $(\alpha, \theta)$-closed graph. Therefore, there exists open set $\mathrm{U} \subset \mathrm{X}$ and $\alpha$-open set $\mathrm{H} \subset \mathrm{Z}$ containing x and $g(\mathrm{y})$, respectively, such that $f(\mathrm{Cl}(\mathrm{U})) \cap \mathrm{H}=\phi$. The $\alpha$-strongly $\theta$ continuity of $g$ implies that there is an open set V of Y such that $g(\mathrm{Cl}(\mathrm{V}))$ $\subset \mathrm{H}$. Therefore, we have $f(\mathrm{Cl}(\mathrm{U})) \cap g(\mathrm{Cl}(\mathrm{V}))=\phi$. This establishes that $(\mathrm{Cl}(\mathrm{U}) \times \mathrm{Cl}(\mathrm{V})) \cap \mathrm{E}=\phi$, which implies that $(\mathrm{x}, \mathrm{y}) \notin \mathrm{Cl}_{\theta}(\mathrm{E}) . \mathrm{So}, \mathrm{E}$ is $\theta-$ closed in $\mathrm{X} \times \mathrm{Y}$.

Corollary 5.1. If Y is an Hausdorff space and $f, g: \mathrm{X} \rightarrow \mathrm{Y}$ are $\alpha$-strongly $\theta$-continuous function, then the set $\{(\mathrm{x}, \mathrm{y}): f(\mathrm{x})=g(\mathrm{y})\}$ is $\theta$-closed in $\mathrm{X} \times$ X.

Proof. Follows from Theorem 5.1 and Theorem 16 of [7].
Theorem 5.2. If $f: \mathrm{X} \rightarrow \mathrm{Y}$ is any function with $\theta$-closed point inverses such that the image of closure of each open set is $\alpha$-closed, then $f$ has $(\alpha, \theta)$ closed graph.
Proof. Let $(\mathrm{x}, \mathrm{y}) \in(\mathrm{X} \times \mathrm{Y}) \backslash \mathrm{G}(f)$. Then $\mathrm{x} \notin f^{-1}(\mathrm{y})$ and since $f^{-1}(\mathrm{y})$ is $\theta$-closed, there exists an open set U containing x such that $\mathrm{Cl}(\mathrm{U}) \cap f^{-1}$ (y) $=\phi$. By assumption $f(\mathrm{Cl}(\mathrm{U}))$ is $\alpha$-closed. Since $\mathrm{y} \notin f(\mathrm{Cl}(\mathrm{U}))$, there is an $\alpha$-open set H in Y containing y such that $f(\mathrm{Cl}(\mathrm{U})) \cap \mathrm{H}=\phi$. Thus $f$ has $(\alpha, \theta)$-closed graph.

Theorem 5.3. Let $f: X \rightarrow Y$ be a function with ( $\alpha, \theta$ )-closed graph, then for each $\mathrm{x} \in \mathrm{X},\{f(\mathrm{x})\}=\cap\{\alpha \mathrm{Cl}(f(\mathrm{Cl}(\mathrm{U})))$ : U is an open set containing x$\}$ Proof. Let the graph of the function be $(\alpha, \theta)$-closed. If $\{f(\mathrm{x})\} \neq \cap\{\alpha \mathrm{Cl}(f(\mathrm{Cl}(\mathrm{U})))$ : U is an open set containing x$\}$.

Let $\mathrm{y} \neq f(\mathrm{x})$ such that $\mathrm{y} \in \cap\{\alpha \mathrm{Cl}(f(\mathrm{Cl}(\mathrm{U})))$ : U is an open set containing $\mathrm{x}\}$. This implies that $\mathrm{y} \in \alpha \mathrm{Cl}(f(\mathrm{Cl}(\mathrm{U})))$ for each open set containing x ; it means that, for each $\alpha$-open set V containing y in $\mathrm{Y}, \mathrm{V} \cap f(\mathrm{Cl}(\mathrm{U})) \neq \phi$. That contradicts Definition 5.1. Thus $\mathrm{y}=f(\mathrm{x})$.

Theorem 5.4. Let $f: \mathrm{X} \rightarrow \mathrm{Y}$ be a function with ( $\alpha, \theta$ )-closed graph. If E is quasi H -closed in X , then $f(\mathrm{E})$ is $\alpha$-closed in Y.
Proof. Let E be a quasi H -closed in X . Suppose that $f(\mathrm{E})$ is not $\alpha$-closed in Y. Let $\mathrm{y} \notin f(\mathrm{E})$. Therefore, $\mathrm{y} \neq f(\mathrm{x})$ for each $\mathrm{x} \in \mathrm{E}$. Since $\mathrm{G}(f)$ has $(\alpha, \theta)$-closed, for each $x \in E$, there exists open set $U_{x}$ and $\alpha$-open set $H_{x}$ containing x and y , respectively such that $f\left(\mathrm{Cl}\left(\mathrm{U}_{\mathrm{x}}\right)\right) \cap \mathrm{H}_{\mathrm{x}}=\phi$, for each $\mathrm{x} \in$ E. The family $\mathbf{Q}=\left\{U_{x}: x \in E\right\}$ is an open cover of $E$. Since $E$ is quasi $H-$

$\mathrm{E} \subset \bigcup_{i=1}^{n} \mathrm{Cl}\left(\mathrm{U}_{\mathrm{x}(\mathrm{i})}\right)$. Put
$\mathrm{H}=\bigcap_{i=1}^{n} \mathrm{H}_{\mathrm{x}(\mathrm{i})}$. Then, $f(\mathrm{E}) \cap \mathrm{H} \subset \bigcup_{i=1}^{n}\left(f\left(\mathrm{Cl}\left(\mathrm{U}_{\mathrm{x}(\mathrm{i})}\right)\right)\right) \cap \mathrm{H} \subset \bigcup_{i=1}^{n}\left(f\left(\mathrm{Cl}\left(\mathrm{U}_{\mathrm{x}(\mathrm{i})}\right)\right) \cap \mathrm{H}_{\mathrm{x}(\mathrm{i})}\right)=\phi$.
Since H is an $\alpha$-open set containing $\mathrm{y}, \mathrm{y} \notin \alpha \mathrm{Cl}(f(\mathrm{E}))$. Therefore, $\alpha \mathrm{Cl}(f(\mathrm{E})) \subset f(\mathrm{E})$, which implies that $f(\mathrm{E})$ is $\alpha$-closed.

Corollary 5.2. The image of any quasi H -closed space in any space is $\alpha$ closed under functions with $(\alpha, \theta)$-closed graphs.

Theorem 5.5. Let $f: \mathrm{X} \rightarrow \mathrm{Y}$ be given. Then $\mathrm{G}(f)$ is $(\alpha, \theta)$-closed graph if and only if for each filter base $\Psi$ in $\mathrm{X} \theta$-converging to some p in X such that $f(\Psi) \alpha$-converges to some q in Y holds, $f(\mathrm{p})=\mathrm{q}$.
Proof. Suppose that $\mathrm{G}(f)$ is $(\alpha, \theta)$-closed graph and let $\Psi=\left\{\mathrm{E}_{\delta}: \delta \in \nabla\right\}$ be a filter base in X such that $\Psi \theta$-converges to p and $f(\Psi) \alpha$-converges to q . If $f(\mathrm{p}) \neq \mathrm{q}$, then $(\mathrm{p}, \mathrm{q}) \notin \mathrm{G}(f)$. Thus, there exists an open set $\mathrm{U} \subset \mathrm{X}$ and $\alpha$-open set $\mathrm{V} \subset \mathrm{Y}$ containing p and q , respectively, such that $(\mathrm{Cl}(\mathrm{U}) \times$ $\mathrm{V}) \cap \mathrm{G}(f)=\phi$. Since $\Psi \quad \theta$-converges to p and $f(\Psi) \alpha$-converges to q , there exists an $\mathrm{E}_{\delta} \in \Psi$ such that $\mathrm{E}_{\delta} \subset \mathrm{Cl}(\mathrm{U})$ and $f\left(\mathrm{E}_{\delta}\right) \subset \mathrm{V}$. Consequently, $(\mathrm{Cl}(\mathrm{U}) \times \mathrm{V}) \cap \mathrm{G}(f) \neq \phi$, which is a contradiction.

Conversely, assume that $\mathrm{G}(f)$ is not $(\alpha, \theta)$-closed graph. Then, there exists a point $(p, q) \notin G(f)$ such that for each open set $U \subset X$ and each $\alpha$-open set $\mathrm{V} \subset \mathrm{Y}$ containing p and q , respectively, holds $(\mathrm{Cl}(\mathrm{U}) \times \mathrm{V}) \cap \mathrm{G}(f) \neq \phi$. Let $\left\{\mathrm{U}_{\delta}: \delta \in \nabla_{1}\right\}$ be the set of all open sets of X containing p . Define $\Psi_{1}=\left\{\mathrm{Cl}\left(\mathrm{U}_{\delta}\right): \delta \in \nabla_{1}\right\}$,
$\Psi_{2}=\left\{\mathrm{V}_{\beta}: \mathrm{V}_{\beta}\right.$ is an $\alpha$-open set containing q and $\left.\beta \in \nabla_{2}\right\}$
$\Psi_{3}=\left\{\mathrm{E}(\delta, \beta): \mathrm{E}(\delta, \beta)=\left(\mathrm{Cl}\left(\mathrm{U}_{\delta}\right) \times \mathrm{V}_{\beta}\right) \cap \mathrm{G}(f),(\delta, \beta) \in \nabla_{1} \times \nabla_{2}\right\}$ and $\Psi=\left\{\Psi^{*}(\delta, \beta):(\delta, \beta) \in \nabla_{1} \times \nabla_{2}\right\}$, where
$\Psi^{*}(\delta, \beta)=\left\{\mathrm{x} \in \mathrm{U}_{\mathrm{x}}:(\mathrm{x}, f(\mathrm{x})) \in \mathrm{E}(\delta, \beta)\right\}$. Then $\Psi$ is a filter base in X with property that $\Psi \theta$-converges to $\mathrm{p}, f(\Psi) \alpha$-converges to q , and $f(\mathrm{p}) \neq \mathrm{q}$. This completes the proof.

Corollary 5.3. A function $f: \mathrm{X} \rightarrow \mathrm{Y}$ has $(\alpha, \theta)$-closed graph if and only if for each net $\left\{\mathrm{x}_{\gamma}\right\}$ in X such that $\mathrm{x}_{\gamma} \rightarrow \theta \mathrm{p} \in \mathrm{X}$ and $f\left(\mathrm{x}_{\gamma}\right) \rightarrow \alpha \mathrm{q} \in \mathrm{Y}$ holds, $f(\mathrm{p})=\mathrm{q}$.
