Abstract

The study investigates the effects of pomegranate peel extracts on some virulence factors such as the production of some enzymes produced by *Proteus* spp isolated from different clinical samples. Among 310 different clinical samples, 48 isolates of proteus were obtained, 14 isolates (29.16%) were obtained from urine, 15 isolates (31.25%) were obtained from stool, 7 isolates (14.58%) from ear swabs, 4 isolates (8.33%) were obtained from wounds, 5 isolates (10.41% (from burns and 3 isolates) 6.25%) of the high cervical. The study showed that from 48 isolates of *Proteus* spp 25 isolates (52.08%) identified as *P.mirabilis*, 15 isolates (31.25%) of *P. penneri*, while 8 isolates of *P. vulgaris* were obtained with a percentage of (16.66%) and it was found that 18 isolates (72%) of *P.mirabilis* isolates were positive for the production of beta-lactamase enzyme, 24 isolates (96%) are positive for proteases and 14 isolates (56%) produced lipase, while 13 isolates from *P. penneri* (86.66%) produced beta-lactamases and proteases and 10 isolates (66.66%) produced lipase, also found that 5 isolates (62.5%) of *P. vulgaris* produced Beta-lactamase and all the isolates (100%) produced protease while 7 isolates (87.5%) produced lipase. It was found that the hot aqueous extract of pomegranate peels inhibited the production of beta-lactamase enzyme in 4 out of 7 isolates that produced this enzyme, while all tested isolates did not produce lipase by using extracts of pomegranate peel extracts. The isolates lost their ability to produce protease enzyme, except for two isolates that were not affected by extracts of pomegranate peel fruits.

1. Introduction:

Proteus spp is Gram-negative bacilli that are highly motile most of the time, and their shape may change. They have the property of seizing the culture medium in successive concentric waves, and these waves form a membrane with which it is impossible to obtain single colonies [1]. The (Swarming) gives a weighted guess to determine the identity [2] and all species of proteus characterized by the production of highly effective urease enzyme [3].

Proteus spp is present on the decaying tissues of animals. It is abundant in sewage, soil [4], and that it is a normal flora

in the digestive system of humans and some animals [5] [6]. It is similar to the characteristics of Enterobacteriaceae. It ferments some sugars such as glucose, mannose, sucrose, and galactose. It also does not ferment lactose and is facultative anaerobic [3],[7].

Beta-lactamase enzymes have received great attention from researchers, as they are the cause of the failure of many antibiotics used to control various infections, especially among hospitalized patients. These enzymes attack the beta-lactam ring present in the nucleus of penicillins and cephalosporins it is breaking the amide bond in them to turn these antibiotics into an inactive compound[8].

Protease enzymes are one of the virulence factors for proteus[9]. One of these types of protein-degrading enzymes is the Metalloprotease enzyme, where this enzyme works to

analyze proteins that contain metal ions in their composition, such as Na⁺, K⁺, which are essential in pathogenesis [10] Proteus secretes the enzyme lipase [11][12], which includes lipolytic enzyme (general) Lipases and specialized enzyme phospholipases. Lipase enzymes work to break down the ester bonds that bind fatty acids with glycerol, producing a molecule of glycerol and fatty acids [3]. The study aimed to investigate the ability of pomegranate peel extracts to influence the production of some enzymes produced by Proteus spp isolated from different clinical samples.

2. Materials and Methods:

2.1 Sample Collection and Culturing:

The study included the collection of urine samples, stool, high cervical swabs, ear swabs, wounds, and burns from patients admitted to Kirkuk General Hospital and Azadi Teaching Hospital in Kirkuk city. 310 samples were collected. Samples were transferred to the laboratory for isolation and diagnosis of bacteria, according to the methods approved in [3][13][14]. Samples were collected according to what was mentioned in [15]. The diagnosis was confirmed using the Rapid ONE system.

2.2 Beta-lactamase Production:

The test was used to detect the ability of Proteus spp to produce this enzyme, the iodometric method used as stated in [15]. (0.1) of Penicillin G solution at a concentration of (6) $\mu\text{g}/\text{ml}$ was added to test tubes containing the bacterial suspension at the age of (18-24) hours. The tubes were shaken and the mixture was left for one hour at a temperature of 37°C. Two drops were added to each tube of the prepared starch solution, then a drop of iodine reagent solution was added to each tube. The tubes were mixed well and left for (5) minutes at laboratory temperature. The disappearance of the dark blue or violet colour within less than 10 seconds indicates the positive result for the production of β -lactamase enzymes.

2.3 Protease production:

The isolates were cultured on a medium of fermentation and oxidation medium. The dishes were incubated at a temperature of (37) C for (24) hours. The appearance of a clear zone around the developing colonies indicates the production of the protease enzyme [15].

2.4 Lipase production:

Lipase production medium inoculated with young colonies of Proteus isolates and incubated at (37) oC for (24-48) hours. The production of lipase enzyme was detected by immersing the medium in a sufficient amount of CuSO₄ saturated solution for (20) minutes, then the dish was dried after removing the excess of the solution by placing it in the incubator for a short period. The appearance of blue-green colour around the colonies indicates the activity of the lipase enzyme [15].

2.5 Collection and preparation of pomegranate peel:

Pomegranate fruits were obtained from the local markets in the Kirkuk city, the peels were separated from the rest of the fruit parts, and then the peels were sterilized with a solution of sodium hypochlorite at a concentration of (1%) free chlorine. [16] was then washed with sterile distilled water, dried with a dry paper, and dried using an electric oven at a temperature of 50 °C for 48 hours, then it was ground using an electric grinder until a fine powder was obtained and kept in plastic containers until use.

2.6 Pomegranate peel extracts preparation:

2.6.1 Alcoholic extract:

The alcoholic extract was prepared using ethanol alcohol 98% as a solvent [17]. The extract was prepared when fruit was purchased from the local market at Kirkuk City. One kilogram of fresh peel was cut into small pieces then mixed in a mechanical blender with 98% ethanol and left at room temperature for 72 h. The extract was filtered through a filter paper and concentrated to dryness under reduced pressure in a rotary evaporator at 40–50oC.

2.6.2 water extract:

The cold and hot aqueous extract was obtained according to what was mentioned in the previous paragraph with the replacement of alcohol with water

2.6.3 chloroform extract:

The chloroform extract was prepared as mentioned in the (previous) paragraph, except for using chloroform 98% as a solvent instead of water, and after mixing the extract with a magnetic stirrer it was left for several hours at room temperature. Three separated parts appear. These parts were then dried in an electric oven at a temperature of 50°C, and the sensitivity of the isolates was tested for each of them.

2.7 Detection of alkaloids:

Dissolve 5 g of the sample in 200 ml of a mixture of acetic acid and ethanol in a ratio of (15:1) and gradually add ammonium hydroxide until the precipitate is formed, filter the solution, dissolve the precipitate, filter again and separate the precipitate, which represents the alkaloid [18].

2.8 Detection of flavonoids:

10 g of the plant sample was added to 100 ml of 80% methanol alcohol and filter the solution with filter paper. Whatman NO 42 extract evaporated and the weight of the precipitate representing the flavonoids present in the sample [18].

2.9 Sensitivity test to pomegranate peel extracts:

Agar well diffusion method was used in this test [19]. The agar plate surface is inoculated by spreading a volume of the microbial inoculum equivalent to 0.5 MacFarland tube over the entire agar surface. Then, a well with a diameter of 6 mm is punched with a sterile cork borer and a volume (70

μL) of the extract is added to the well. Then, agar plates are incubated in an incubator.

2.10 Effect of pomegranate peel extracts on the production of beta-lactamase enzyme:

The sub MIC of pomegranate peel extracts mixed with the nutrient broth medium and inoculated with the isolates under study and placed in the incubator at a temperature of (37°C) for (24) hours, Then the production of beta-lactamase enzymes was detected.

2.11 Effect of pomegranate peel extracts on production of Protease:

The sub MIC of pomegranate peel extracts mixed with the medium to investigate the production of protease enzyme and inoculated with the isolates under study and incubated at a temperature of (37°C) for (24) period, the production of protease enzyme was detected in the presence of clear areas around the colonies

2.12 Effect of pomegranate peel extracts on the production of lipase enzyme:

The sub MIC of pomegranate peel extracts mixed with the medium for detecting lipase production and inoculated with the isolates under study and incubated at a temperature of (37°C) for 24 hours. The medium was filled with a sufficient amount of a solution saturated with copper sulfate CuSO_4 for (20) minutes, then the plate was dried after removing the excess of the solution by placing it in the incubator for a short period. The appearance of greenish-blue colour around the developing colonies indicates the activity of the lipase enzyme.

3. Results:

310 samples were obtained from people who were suffering from various diseases, from those who were admitted to Kirkuk General Hospital and Azadi Teaching Hospital, from both sexes. The samples included. Urine, stools, ear swabs, wounds swab, burn swabs and high cervical dried swabs, as shown in Tabel 1.

Table 1. numbers and percentages of samples.

2	Stool	25	8.06
3	Ear swab	58	18,70
4	wounds	26	8,38
5	Burns	23	7,41
6	high cervical	35	11,29
Total		310	

Various tests were carried out on the isolates under study, which showed the characteristic of swarming on blood and non-lactose fermenting on McConkey medium, which produces the smell of rotting fish, and it appeared under the microscope in the form of the gram-negative bacillus of varying lengths.

To confirm the diagnosis, a RapID ONE system was used supplied by (Remel company) which is characterized by ease and speed of diagnosis, and the results were identical and confirmed to the results of biochemical tests. from 310 samples 48(15.45%) *Proteus* spp isolated for different clinical samples as shown in Table 2 , whereas in another study the percentage of *Proteus* by 4% were isolated[20].

Table 2. Number and percentages of *Proteus* spp in different clinical samples.

	Samples	No.	%
1	Urine	14	29.16
2	Stool	15	31.25
3	Ear swab	7	14.58
4	Wound	4	8.33
5	Burns	5	10.41
6	high cervical	3	6.25
Total		48	

After the diagnosis, it was noted that the isolates of *P.mirabilis* were the most common as its number reached 25 isolates with a percentage (52,08%) of the total 48 *Proteus* isolates. As for *P. penneri* isolates, it reached 15 isolates (31,25%), and the number of *P.vulgaris* isolates reached 8 (16,66%).) as in Figure 1.

Figure 1. Percentages of the *Proteus* spp isolates under study.

The results of this study showed the prevalence of the *Proteus mirabilis* in urine, stool and vaginal swabs compared to *P. penneri* and *P. Vulgaris*, as shown in Table 3. As the percentage of this species in urinary tract infections was about (64.28%), while *P.penneri* and *P.vulgaris* percentages were about (21.42%) (14.28%), respectively, and these results are very close to the results of [2] [21], who indicated that *P.*

mirabilis more common than the *P. vulgaris* and *P. penneri* in clinical samples.

Proteus was isolated in a percentage (31.25%) of the diarrhoea cases, and this result was higher than the one obtained from the study of [22], where isolated this bacterium from diarrhoea cases with a percentage of (7.11%). The most common *proteus* species of cases of diarrhoea are *P. mirabilis*, which represents about (53.33%), the high percentage of *Proteus* in cases of diarrhoea may be attributed to being part of the normal flora found in the digestive system, as *P. mirabilis* is present in a (17%) and *P. vulgaris* in a percentage (5%) in the stools of healthy people [23] and that the Alkaline environment of the intestine helps to multiply and increase the normal flora in it, but the excessive reproduction of bacteria as a result of the weakness of the body may lead to the occurrence of infections of the gastrointestinal tract and thus the occurrence of diarrhoea which maybe because of the entrance of *proteus* with foods or drinks in the absence of personal and general hygiene.

Concerning ear infections, the percentage of *Proteus* spp isolates that appeared in this study is (14.58%) of the total 48 isolates of *Proteus* spp and this result is close to the results of [24], as the *Proteus* spp were isolated from ear infections with percentages (12.9%), that the high percentage of isolation that was obtained may be due to the presence of several factors that contribute to ear infection, including infection of the upper respiratory tract with viruses that lead to blockage of the Eustachian Tube and thus fluid collects inside the ear, and any small wound resulting from excessive cleaning of the ear canal and using a cotton swab or any sharp tool prepares the situation for bacterial growth in addition to the use of earplugs and headphones continuously leads to an increase in the incidence of infection

The results showed the isolation of *Proteus* spp from the female reproductive system with a percentage of (6.25%), which was represented by isolation of *P. mirabilis* and *P. vulgaris* with percentages (33.33%) and (66.66%) respectively, because this bacterium is one of the bacteria present as a normal flora in the human digestive system, due to the proximity of the anus to the female genital, which leads to exposure to infections by the contaminating bacteria for that region, just as the vagina and cervix are in a normal acidic environment due to the presence of the normal bacterial flora in them, but as a result of the menstruation, the PH changes to alkaline, which increases the chance of infection by opportunistic bacteria, and these results are higher than the results obtained by [25], which isolated *Proteus* spp from the female reproductive system with a percentage of (4.9%).

The results for wound infections showed isolation of *Proteus* spp with a percentage of (8.33%), which belongs to the two species *P. mirabilis* and *P. penneri*, and this result is almost close to what was reached [26] which isolated *Proteus* by (13.6%), and these percentage differences may be due to the

difference in the geographical location of the source of the samples. The incidence of wound infection may be attributed to the high sensitivity of the exposed area of the wound to microbial invasion, whether the wound was spontaneous or resulting from a surgical operation. Just as the wounds become more susceptible to infections by not following the correct methods in terms of hygiene, and by not paying attention to sterilization rules by hospital staff, as well as other factors related to the personal hygiene of the patient himself and the medical staff.

About burn infections, *Proteus* bacteria were isolated with a percentage of (10.41%), and this result is less than the result obtained by [27] which isolated *Proteus* bacteria from burns with a percentage of (24%).

The production of the enzymes is one of the important mechanisms of resistance to beta-lactam antibiotics in members of the Enterobacteriaceae family. Table 5 showed the ability of most isolates of *Proteus* to produce beta-lactamase enzymes, as the number of isolates reached *P. mirabilis* isolates producing 18 (72%) isolates. As for *P. penneri* isolates, 13 (86.66%) were enzyme-producing, while the number of *P. vulgaris* isolates producing beta-lactamase was about 5 (62.5%). The results of the detection of protease enzyme

Figure 2. A non-protease producing enzyme.
B producer of the protease enzyme.

production by the *Proteus* spp an understudy showed that all *P. vulgaris* were produced this enzyme, and 24(96%) of the *P. mirabilis* Enzyme-producing while *P. penneri* produced protease in 13 (86.66%). Table 4 and Figure 2.

Table 6 and Figure 3 and Figure 4 showed lipase production. 14(56%), 10(66.66%), and 7(87.5%) belonging to *P. mirabilis*,

**Figure 3.** produce lipase.**Figure 4.** not produces lipase.

(+: enzyme-producing, -: non-enzyme-producing) Figure 5 showed the effect of aqueous (cold and hot water) and alcoholic extracts of pomegranate peels extracts (at a concentration of 100 mg/ml) on proteus spp. The results showed a difference in the effectiveness of the extract from one isolate to another in the three extracts. The zone of the inhibition

appears to be (21-33 mm) in the hot aqueous extract against several bacteria, while the diameters of the inhibition zone in the cold aqueous extract and alcoholic extract ranged from (20-32 mm) and this result is greater than the study of v[28], and three isolates showed resistance to the three extracts.

The results indicate that the active substance of this plant

has a solubility in water, as the diameter of the growth inhibition zone ranged from (20-32 mm) in the cold aqueous extract (at a concentration of 100 mg/ml) and the diameter of the growth inhibition zone ranged from (21-33 mm) in The hot aqueous extract (at a concentration of 100 mg/ml), the results of the current study agreed with what was indicated, [29] by the effect of hot water extracts on some bacterial isolated from patients with pharyngitis, tonsillitis, wounds, some skin infections and bronchitis, the bacteria isolated from those cases included *Micrococcus* spp. *Staphylococcus aureus*, *Staphylococcus epidermidis*, *Streptococcus pyogenes*, *Streptococcus pneumoniae*, all of which showed sensitivity to the extracts of pomegranate peels used and with different degrees of effect from one species to another. Also, it appears that the hot aqueous extract of pomegranate peel had an inhibitory effect on the growth of *P.aeruginosa* and *E.coli* [30].

Lime (2012)[31] pointed out that the phenolic compounds present in the pomegranate peel interfere with the function of the cell membrane in bacteria and affect the synthesis of DNA and RNA and inhibit the synthesis of proteins, while alkaloids, some of them affect the DNA of bacteria by getting stuck in the strands of bacterial DNA.

As for the alcoholic extract (ethanol 98%) of the peels of pomegranate fruits also had a great effect in inhibiting the growth of proteus, as the diameter of the inhibition zone

ranged from (20-32 mm), which is consistent with what was indicated by [32], who confirmed that the alcoholic extract of pomegranate peels had high inhibitory activity against gram-negative and gram-positive bacteria. [33] also indicated that the ethanolic extract of the peels of pomegranate fruits has an inhibitory activity on the growth of the bacteria (*P.mirabilis*, *P.vulgaris*, *Pseudomonas* spp., *E.coli*, *Shigella* spp., *Klebsiella* spp., *Citrobacter* spp., *Enterobacter* spp., *Salmonella typhi*, *Salmonella paratyphi*), and the inhibition of bacterial growth may be due to the pomegranate peels containing some substances that dissolve in alcohol.

The results showed the effect of the chloroform extract (chloroform 98%) on the growth of *Proteus* isolates, as three separate layers were obtained when preparing the extract, and the effect of each on the growth of *Proteus* was studied. The range of inhibition zone (10-23 mm) with 9 resistant isolates. The sensitivity of the isolates to this extract is due to the active substances dissolved in water, as the extract contains water by 2%. As for the middle layer (the chloroform layer), all isolates were resistant and did not show any inhibition of the growth of the isolates, while the third layer (insoluble substances in water and chloroform) showed growth inhibition that ranged from (9-25 mm) except for 8 Isolates did not show sensitivity to this extract, and this inhibiting effect of bacterial growth may be attributed to the extract containing active substances against bacterial growth, as this layer contains substances that are insoluble in water and chloroform.

Figure 5. Efficacy of pomegranate peel extracts on *Proteus* spp

- D: water(control).
- E: alcohol ethanol 98%(control)

Alkaloids and flavonoids are effective compounds in inhibiting the growth of bacteria. The results showed the effectiveness of these substances against the growth of *Proteus*. As shown in Figure 6 The diameter of the growth inhibition zone due to alkaloids ranged from (12-25 mm), as alkaloids are the most important medicinal substances in the plant, and from a chemical point of view, they are organic substances of complex composition similar to the presence of an atom N in it, which gives it the characteristics of an alkaline-like substance. It was found that some alkaloids affect bacterial DNA by interfering with bacterial DNA strands, leading to inhibition of their growth [31].

Figure 6. Growth inhibition zones for some extracts
A: flavonoids, B: alkaloids chloroform extract, C: aqueous layer, D: water-insoluble chloroform layer, E: chloroform layer

As for flavonoids, they are phenolic compounds that have the property of antioxidants [34]. also showed an inhibitory effect on the growth of *Proteus*, as the diameter of the isolates inhibition zone ranged from (11-25 mm), except for 4 isolates that were resistant to flavonoids. Figure 6), referring[35]. The inhibitory property of pomegranate peels is because it contains many active substances against the growth of bacteria, including flavonoids. The results of the effects of chloroform extracts showed that three layers were obtained, and the inhibitory activity of the three layers was investigated on the *Proteus* isolates as shown in Figure 6, the diameters of the growth inhibition zone around the first extract (aqueous layer) ranged from (10-23 mm) with 9 resistant isolates. As for the chloroform layer, all isolates were resistant and did not show any inhibition of the growth. The third extract (insoluble substances in water and chloroform) had growth inhibition that ranged from (9-25 mm), except for 8 isolates that did not show sensitivity to this extract.

Figure 7. Lipase -ve treatment with extracts

Figure 9. protease -ve

Figure 8. Lipase +ve treatment with extracts

Figure 10. protease +ve

Twelve isolates from the isolates of the *Proteus* spp under study were nominated, which are characterized by their possession of a group of virulence factors, and the detection of these factors was carried out with their treatment with pomegranate peel extracts simultaneously to observe the effect of the extracts on the virulence factors possessed by these isolates.

The results showed the effect of the hot aqueous extract of pomegranate peels on the production of beta-lactamase enzymes, as it inhibited the production of the enzyme in 4 out of 7 isolates producing this enzyme, while the cold aqueous extract and alcoholic extract did not show any effect on the production of this enzyme, as shown in the Table 7.

The effect of pomegranate peel extracts on the ability of isolates to produce lipase was investigated, as all isolates gave

a negative test result in the presence of the extracts, meaning they lost the ability to produce the enzyme at a concentration of 25 mg/ml as shown in Figures 7,8. The results showed that the isolates lost their viability on the production of protease during treatment with extracts, except for two isolates (out of a total of 12 isolates) that produced the enzyme during treatment with hot aqueous extract as shown in the two Figures 9,10.

The suspension of the production of some enzymes that are considered as virulence factors for *Proteus* by the extracts of pomegranate peels may be due to the pomegranate peels containing many active ingredients such as phenolic compounds that interfere with the membrane function in bacteria and affect the synthesis of DNA and RNA, It works by inhibiting the production of enzymes by their interaction with sulfhydryl groups or by their unspecialized interference with

proteins, in addition to the presence of tannins Known for its inhibitory effect on the production of enzymes, due to the formation of hydrogen bonds with proteins[36] [31].

4. Recommendations:

1. Studying the inhibitory activity of plant extracts and their active components in laboratory animals to ensure the safety of their use without the appearance of side effects when used.
2. Separating the different active ingredients from plants in a pure manner and identifying their chemical structures for the possibility of using them in treatment.
3. peel extracts may be included in drug formulations suitable for the treatment of infections caused by proteobacteria, especially strains that have multiple resistance to antibiotics.

الخلاصة

في هذا البحث نستخدم طريقة الطول الأقصى للأثر (L_{max}) بالاعتمادية الدراسة في تأثير مستخلصات قشور الرمان على إنتاج بعض عوامل الضراوة مثل الإنزيمات التي تنتجها بكتيريا *Proteusspp* المعزولة من عينات سريرية مختلفة. تم جمع 310 عينة سريرية مختلفة ومنها تم الحصول على 48 عزلة من المتقلبات *Proteusspp* اذ تم الحصول على 14 عزلة (29.16) من البول و 15 عزلة (31.25) من البراز و 7 عزلات (14.58) من مسحات الأذن و 4 عزلات (8.33) من الجروح و 5 عزلات (10.41) من الحروق و 3 عزلات (6.25) من عنق الرحم. أوضحت الدراسة أنه من بين 48 عزلة وجد ان 25 (52.08) منها شخصت على انها *P.mirabilis* وتم الحصول على 15 عزلة (31.25) من *P.penerri* ، في حين تم الحصول على 8 عزلات من *P.Vulgaris* بنسبة (16.66) . وجد أن 18 عزلة (72) من عزلات *P.mirabilis* كانت موجبة لإنتاج إنزيم بيتا لاكتاميز، 24 عزلة (96) كانت موجبة للبروتيز و 14 عزلة (56) أنتجت الليبيز، بينما 13 عزلة (86.66) من *P.penerri* أنتجت انزيم البيتا لاكتامازات وانزيم البروتيز و 10 عزلات (66.66) أنتجت الليبيز، كما وجدت أن 5 عزلات (62.5) من *P.vulgaris* أنتجت البيتا لاكتاميز وجميع العزلات (100) أنتجت البروتيز بينما أنتجت 7 عزلات (87.5) الليبيز. وجد أن المستخلص المائي الحار لقشور الرمان ثبت إنتاج إنزيم البيتا لاكتاميز في 4 عزلات من أصل 7 أنتجت هذا الإنزيم، في حين أن جميع العزلات المختبرة لم تنتج الليبيز باستخدام مستخلصات قشر الرمان. فقدت العزلات قدرتها على إنتاج إنزيم البروتيز باستثناء عزلتين لم تتأثرتا بمستخلصات قشور ثمار الرمان.

الكلمات الدالة: قشور الرمان، انزيمات، المتقلبات.
